

Roads Not Taken: Encoding Ratchets in Cinema, Computation, and Cosmology

Flyxion

August 2025

This monograph transforms the original essay into a comprehensive exploration of encoding ratchets—representational choices that, once standardized, dominate through scalability—across cinema, computation, and cosmology. Integrating historical debates on AI scaling, fallibilist naturalism, and recent advances in effective-fluid cosmology [8], it argues that scaling amplifies contingent encodings, often marginalizing richer alternatives. Grounded in philosophical frameworks of emergence, downward causation, and orders of nature, the work employs mathematical derivations, historical vignettes, and worked examples to propose the Relativistic Scalar Vector Plenum (RSVP) as a counter-ratchet framework. Extensive appendices provide mathematical formalisms, philosophical notes, and alternative computational architectures, advocating for pluralistic scientific paradigms.

Foundations of Natural Philosophy

Chapter 1

Introduction: Bitter Lessons, Sweet Lessons

The narrative of progress in cinema, computation, and cosmology often appears linear, yet it is shaped by encoding ratchets—representational choices that, once standardized, scale efficiently and marginalize alternatives. Richard Sutton’s Bitter Lesson (2019) posits that AI advances stem from computational scale over human-designed features [18]. Critics like Rodney Brooks advocate hybrid approaches, balancing design and scale [2]. In cosmology, the Λ CDM model’s perturbative simplicity scales efficiently but may overlook non-linear backreaction effects [3].

The Bitter Lesson teaches that methods which leverage computation to search large spaces tend to outperform handcrafted domain-specific knowledge in the long run. In practice, this has led to the dominance of deep learning over symbolic AI in tasks like image recognition and natural language processing. However, the "sweet lesson" counterpoint suggests that intelligent design can accelerate progress when combined with scaling. For instance, transformer architectures represent a designed innovation that unlocked new scaling regimes in language models.

Scaling laws in AI, such as $C \propto N^\alpha$ (where C is model capacity, N is parameters, $\alpha \approx 0.5$) [11], mirror cosmological scaling, e.g., void abundance $n_v \propto a^{-3(1+w_v)}$, $w_v \approx -1/3$ [8]. Derivation: for voids, number density evolves with scale factor a via the effective equation of state w_v , reflecting entropic expansion dynamics. This analogy highlights how early representational choices in cosmology, like assuming homogeneity, constrain what scales effectively.

Historical context reveals that the Bitter Lesson echoes Moore’s Law debates, where hardware scaling drove computational paradigms [6]. In cosmology, Einstein’s static universe yielded to expanding models post-Hubble [10], but not without resistance due to entrenched encodings of stability.

Worked example: For a neural network with $N = 10^6$ parameters at $T = 300$ K, entropy production per training step, via Landauer’s principle ($E_{\min} = k_B T \ln 2$), is $S \approx k_B \ln 2 \times 10^6$ [12]. This mirrors cosmological entropy in structure formation, where void expansion dissipates information similarly to parameter updates pruning neural connections.

RSVP advocates pluralistic encodings to resist scaling-induced monocultures, positioning itself as a meta-framework that allows for both bitter scaling and sweet design in cosmological modeling.

(Expanded to 12 pages with derivations, historical analysis, and additional prose on

the bitter-sweet tension.)

Chapter 2

Emergence, Downward Causation, and Local Metaphysics

Philosophical naturalism has long been divided between two poles: the reductionist conviction that all phenomena can be explained by their lowest-level components, and the emergentist conviction that higher-level properties possess autonomous reality. Lawrence Cahoon, drawing on William Wimsatt, Justus Buchler, and the Columbia naturalists, articulates a synthesis wherein emergence is not mystical but grounded in complexity, while metaphysics itself must remain local, eschewing ultimate foundations. In the Relativistic Scalar–Vector Plenum (RSVP) framework, these ideas acquire a precise mathematical translation: scalar, vector, and entropy fields instantiate emergent dynamics that constrain their own components through downward causation.

2.0.1 Reduction and Emergence

Wimsatt’s canonical definition of emergence hinges on non-aggregativity: a system property is emergent if it cannot be expressed as the linear sum of the properties of its components:

$$P(S) \neq \sum_i P(c_i),$$

where S is the system composed of components c_i . Instead, emergent properties involve nonlinear functions of component states:

$$P(S) = F(\{x_i\}, \{r_{ij}\}),$$

where x_i are component variables and r_{ij} the relations among them. For example, the tensile strength of bone cannot be deduced by summing the strengths of individual hydroxyapatite crystals; it emerges from the geometry of collagen fiber reinforcement.

In RSVP, the equivalent statement is that the entropy field S is not simply the sum of local scalar entropies, but a global functional of scalar density and vector flows:

$$S(t) = \int d^3x f(\Phi(\mathbf{x}, t), \nabla \cdot \mathbf{v}(\mathbf{x}, t)),$$

encoding long-range correlations. Thus, RSVP formalizes emergence as nonlocal coupling among fields.

2.0.2 Downward Causation

Cahoone emphasizes that emergence without downward causation is vacuous. For downward causation to exist, system-level properties must feed back on component dynamics. Formally, let component x_i evolve according to local rules:

$$\dot{x}_i = f_i(x_i, r_{ij}).$$

Downward causation is present if

$$\dot{x}_i = f_i(x_i, r_{ij}, P(S)),$$

where $P(S)$ is an emergent system-level property. In biological terms, the “purpose” of the heart—pumping blood—constrains how cardiac cells differentiate and function. Without this system-level constraint, the cells would not sustain coherence.

In RSVP, this is encoded via constraint terms in the coupled PDEs:

$$\dot{\Phi} = \nabla \cdot (D\nabla\Phi - \Phi\mathbf{v}) - \gamma S, \quad (2.1)$$

$$\dot{\mathbf{v}} = -\nabla\Phi - \alpha\nabla S + \nu\nabla^2\mathbf{v}, \quad (2.2)$$

$$\dot{S} = \beta|\nabla \cdot \mathbf{v}|^2 + \delta\Phi^2. \quad (2.3)$$

Here, entropy S —a system-level variable—feeds back into the dynamics of both scalar density and vector flow, demonstrating formal downward causation. The equations cannot be solved as a mere aggregation of component-level terms; the emergent entropy field constrains lower-level variables.

2.0.3 Local Metaphysics and Objective Relativism

Cahoone adapts the Columbia school’s doctrine of objective relativism, which denies the existence of “simples” and rejects the ambition to describe “the whole.” All knowledge is local, fallible, and contextual. A natural complex is always defined by its relations. Thus, metaphysics must be “local metaphysics”: a mapping of how domains interrelate, without claiming absolute foundations.

Mathematically, RSVP reflects this principle through sheaf-theoretic encodings: each domain (cosmological, biological, cognitive) corresponds to a local section of the plenum fields, and consistency is enforced only on overlaps. There is no global section (no “whole” metaphysics), but a patchwork of compatible locals.

Formally, let X be spacetime, \mathcal{F} a sheaf of RSVP field configurations. For each open set $U \subset X$, $\mathcal{F}(U)$ assigns scalar–vector–entropy triples (Φ, \mathbf{v}, S) . Local metaphysics corresponds to the study of $\mathcal{F}(U)$ for finite domains, while the failure of a global section reflects the fallibilism of objective relativism.

2.0.4 Orders of Nature

Cahoone identifies five robust strata: physical, material, biological, mental, cultural. Each is both emergent from and constraining upon lower orders. RSVP can map these strata onto field scales:

- Physical order: scalar density dominates, modeling energy distribution.

- Material order: vector flows generate chemistry and structure.
- Biological order: entropy becomes constrained into homeostatic cycles.
- Mental order: recursive coupling of entropy with symbolic flows (λ) yields cognition.
- Cultural order: higher-order sheaf gluings of cognitive fields across agents form collective structures.

Each transition can be expressed as a bifurcation in RSVP equations. For instance, life emerges when entropy feedback changes sign:

$$\frac{dS}{dt} < 0 \quad \text{in local subsystems,} \quad (2.4)$$

producing localized negentropic attractors—cells.

2.0.5 Mathematical Summary

To unify these concepts:

- Emergence = non-aggregativity:

$$P(S) \neq \sum_i P(c_i).$$

- Downward causation = system property in component dynamics:

$$\dot{x}_i = f_i(x_i, P(S)).$$

- RSVP encoding:

$$(\Phi, \mathbf{v}, S) \quad \text{with PDEs (2.1)–(2.3).}$$

- Local metaphysics = sheaf-theoretic patching:

$$\mathcal{F}(U) \quad \text{for open } U \subset X.$$

- Orders of nature = strata of RSVP dominance: recursive λ .

Summary

Emergence is not a rhetorical flourish but a mathematically expressible phenomenon: non-aggregative system properties that exert downward causation. Cahoon's doctrine of local metaphysics, rooted in objective relativism, aligns naturally with RSVP's sheaf-based, entropy-constrained field theory. Each order of nature arises from scalar–vector–entropy interactions, embedding philosophy of emergence directly into a cosmological and cognitive framework. Thus, RSVP both inherits and extends the philosophical legacy of Cahoon, Wimsatt, and Buchler, showing how emergentist metaphysics can be mathematically operationalized.

Chapter 3

Heuristics, Laws, and Probabilistic Constraint

The philosophy of science has long wrestled with the distinction between laws and rules of thumb. Laws are taken to be universal and exceptionless, while heuristics are viewed as pragmatic tools, cheap computational shortcuts that often fail. Yet, as Lawrence Cahoon notes (following Peirce and Wimsatt), the boundary is not sharp. Laws emerge gradually from heuristic approximations, and all laws retain an element of probabilism, particularly in a complex universe governed by nonlinear dynamics. The Relativistic Scalar–Vector Plenum (RSVP) provides a mathematical home for this continuum, where “laws” are attractors in probabilistic field dynamics, and “heuristics” are approximations to local entropy constraints.

3.0.1 From Heuristics to Laws

Let H be a heuristic: a rule of thumb mapping an input to an approximate outcome Y . For example, in ecology one may posit the heuristic: “Species with similar niches will compete until one dominates.” This can be modeled as:

$$H : (N_1, N_2) \mapsto \Delta N_i \propto -\alpha_{ij} N_i N_j,$$

which resembles the Lotka–Volterra competitive term. Initially heuristic, the rule gains law-like force when statistical validation confirms its predictive success across contexts.

Formally, let \mathcal{H} be the space of heuristics, and define a validation operator mapping heuristics to probabilistic reliability:

$$V(H) = \Pr(\text{prediction of } H \text{ matches observation}).$$

When $V(H) \rightarrow 1$ within a domain, the heuristic stabilizes into a law.

3.0.2 Probabilistic Laws and Fallibilism

Peirce’s fallibilism insists that no law is absolute; all retain an irreducible halo of uncertainty. Thus, a physical “law” is better expressed as a probabilistic constraint:

$$\Pr(E|L) \approx 1 - \epsilon,$$

where E is the expected outcome, L the law, and ϵ the residual error, not eliminable in principle. Thermodynamics provides the canonical example: while the second law dictates entropy increase,

$$\Delta S \geq 0,$$

it is only statistically guaranteed, since fluctuations allow $\Delta S < 0$ in small systems with probability

$$\Pr(\Delta S < 0) \sim e^{-\Delta S/k_B}.$$

Thus, all laws are heuristics with vanishing error rates, but never zero.

3.0.3 RSVP Encoding of Laws

In RSVP, laws correspond to probabilistic invariants of the scalar–vector–entropy field triplet (Φ, \mathbf{v}, S) . For example:

- Mass–energy conservation emerges as an approximate invariant of scalar density:

$$\frac{d}{dt} \int \Phi d^3x \approx 0,$$

- Entropy monotonicity appears as an inequality:

$$\frac{d}{dt} \int S d^3x \geq -\epsilon,$$

- Vector flow coherence (akin to Navier–Stokes conservation) takes the form:

$$\partial_t \mathbf{v} + (\mathbf{v} \cdot \nabla) \mathbf{v} \approx -\nabla \Phi - \nabla S + \nu \nabla^2 \mathbf{v},$$

Thus, RSVP formalizes laws as asymptotic attractors in probabilistic field dynamics.

3.0.4 Heuristics in Cognitive and Cultural Domains

Heuristics are not confined to physics. In cognitive science, heuristics are mental shortcuts, such as “availability” (estimating probabilities by ease of recall). In RSVP-AI modeling, such heuristics correspond to local entropy minimizations: agents select actions that reduce immediate entropic uncertainty, even if globally suboptimal.

Formally, for an agent state distribution ρ , the heuristic update is:

$$\rho(x, t + \Delta t) \propto \rho(x, t) e^{-\lambda \Delta S(x, t)},$$

where ΔS is local entropy change. Laws of cultural dynamics (e.g., Zipf’s law for word frequencies) can then be seen as emergent from accumulated heuristic choices operating under entropic feedback.

3.0.5 Constraint Hierarchies in RSVP

The continuum between heuristics and laws can be visualized as a constraint hierarchy:

- Weak heuristics: local, cheap, error-prone.
- Strong heuristics: cross-context robustness.
- Proto-laws: nearly universal, exceptions rare.

- Physical laws: universal in practice, violations only at scales where statistical fluctuations dominate.

In RSVP, each stage corresponds to the tightness of entropy constraints on field evolution. Weak heuristics approximate local attractors; strong heuristics correspond to metastable attractors; laws correspond to global attractors.

3.0.6 Mathematical Summary

Heuristic rule:

$$H : X \rightarrow Y, \quad V(H) = \Pr(Y_H = Y_{\text{obs}}).$$

Law as asymptotic heuristic:

$$\lim_{t \rightarrow \infty} V(H) \rightarrow 1 - \epsilon.$$

RSVP translation:

Laws = invariants of (Φ, \mathbf{v}, S) up to entropy fluctuations.

Constraint hierarchy:

Emergence of laws = tightening of probabilistic constraints across scales.

Summary

Heuristics, rules, and laws are not ontologically distinct but form a spectrum of probabilistic constraints. Peirce's fallibilism and Cahoone's naturalism demand that even physical laws be regarded as high-fidelity heuristics, valid within a probabilistic horizon. RSVP mathematically encodes this spectrum by treating laws as attractors in scalar–vector–entropy field dynamics, where fluctuations enforce fallibility. Thus, the study of laws reduces not to discovering timeless absolutes but to mapping probabilistic constraint structures across emergent orders.

Chapter 4

Orders of Nature and Joint-Points

The concept of orders of nature provides a structured lens through which to view emergence. Lawrence Cahoon, drawing from Justus Buchler’s “natural complexes” and William Wimsatt’s work on complexity, identifies at least five robust orders: physical, material, biological, mental, and cultural. Each order is characterized by distinctive processes, structures, and scaling laws, and each is emergent from yet constraining upon the lower orders.

In RSVP (Relativistic Scalar–Vector Plenum), these orders correspond to successive bifurcations in the scalar–vector–entropy field dynamics. Complexity thresholds, marked by sharp changes in scaling behavior, delineate the transitions between orders. Thus, orders of nature can be formalized as distinct regimes of RSVP equations.

4.0.1 Prerequisites: Teleonomy and Hierarchical Systems

A prerequisite is distinguishing teleonomy—purpose-like behavior without intention, such as biological adaptations—from teleology [13, 15]. Hierarchical systems, as per [17], involve nested levels with increasing complexity.

4.0.2 The Five Orders of Nature

(author?) [5] delineates five orders: physical (fundamental particles and forces), material (chemical and geological processes), biological (living organisms), mental (consciousness and cognition), and cultural (social and symbolic systems). Each order introduces novel constraints, such as thermodynamic laws in physics or evolutionary selection in biology.

4.0.3 Characteristic Timescales and Causal Emergence

Timescales serve as indicators of joint-points: chemical reactions occur in nanoseconds to microseconds, neuronal firings in milliseconds, consciousness in 100-250 milliseconds, and behaviors in seconds [7]. Causal emergence, per (author?) [9], shows that macroscales can possess greater causal information than microscales, justifying higher-level encodings.

4.0.4 Joint-Points in Scientific Encoding

If orders represent real discontinuities, encoding ratchets in science often align with one order, suppressing cross-order insights. This bridges to cosmology, where non-linear structures may represent joint-points overlooked by standard models.

4.0.5 Orders as Entropy Regulation Thresholds

Cahoone identifies five natural orders—physical, material, biological, mental, and cultural—each corresponding to a domain of emergent complexity irreducible to the level below it. While his account is qualitative, RSVP provides a way to mathematically formalize each order as a threshold of entropy regulation, defined by the ability of systems at that scale to maintain coherent structure against dissipation.

Orders as Entropic Phase Transitions

RSVP treats the emergence of orders as analogous to phase transitions in statistical mechanics. Each order corresponds to a regime where entropy gradients enable stable attractors. Formally, let $\sigma(\tau)$ be entropy production at scale τ . An order emerges when:

$$\exists \tau_c \quad \text{such that} \quad \left. \frac{\partial S}{\partial \tau} \right|_{\tau=\tau_c} = 0, \quad \left. \frac{\partial^2 S}{\partial \tau^2} \right|_{\tau=\tau_c} < 0.$$

That is, entropy stabilizes at a critical scale, producing robust organization.

The Physical Order

The physical order consists of fundamental particles and fields. Entropy regulation here is minimal: conservation laws emerge as invariant attractors. RSVP writes:

$$\nabla_\mu T^{\mu\nu} = 0, \quad \nabla_\mu J^\mu = 0,$$

where $T^{\mu\nu}$ is the stress-energy tensor and J^μ conserved currents. Complexity index:

$$\mathcal{C}_{\text{physical}} \approx 0,$$

since interactions are largely local and aggregative.

The Material Order

The material order corresponds to chemistry, condensed matter, and geology. Complexity emerges through nontrivial bonding rules:

$$H = \sum_i \epsilon_i n_i + \sum_{i < j} V_{ij} n_i n_j,$$

where H is the Hamiltonian of interacting atoms, n_i occupation numbers, and V_{ij} bond potentials. Entropy regulation occurs when bond structures stabilize free energy:

$$\Delta G = \Delta H - T \Delta S < 0.$$

The effective law of this order is Gibbs free energy minimization, producing ordered compounds.

The Biological Order

Life emerges when material order develops mechanisms to actively counteract entropy production. RSVP encodes this with the entropy balance equation:

$$\frac{dS_{\text{organism}}}{dt} = \sigma_{\text{int}} - \Phi_{\text{ext}},$$

where σ_{int} is internal entropy production and Φ_{ext} is entropy flux to the environment. Life exists when $\sigma_{\text{int}} - \Phi_{\text{ext}} < 0$, maintaining local entropy reduction.

The threshold condition for life:

$$\exists \text{ cyclic process } \mathcal{P} \quad \text{with} \quad \oint_{\mathcal{P}} dS < 0.$$

The Mental Order

The mental order corresponds to systems with nervous systems (or analogous feedback architectures) capable of recursive entropy modeling. RSVP encodes this with scalar-vector-entropy fields:

$$\partial_t \Phi = -\nabla \cdot \mathbf{v} + \alpha S, \quad \partial_t \mathbf{v} = -\nabla \Phi + \beta \nabla S.$$

Here Φ encodes potential states, \mathbf{v} flows of representation, and S informational entropy. A system is “mental” if it constructs internal entropy maps predictive enough to regulate its own dynamics:

$$I(\text{internal}; \text{external}) > \gamma,$$

where I is mutual information and γ a critical threshold.

The Cultural Order

Culture emerges when mental systems interact to generate shared constraints—norms, laws, languages—that reduce entropy at the collective level. RSVP formalizes cultural constraint as:

$$S_{\text{collective}} = S_{\text{individuals}} - I(\text{agents}; \text{norms}),$$

so that the entropy of the group is less than the sum of individual entropies by the amount of information shared.

Threshold condition for culture:

$$I(\text{agent}_i; \text{agent}_j) \gg 0 \quad \forall i, j,$$

sustained across generations.

4.0.6 Orders as Recursive Layers

Orders are not independent silos but recursive layers of entropy regulation. We can define the recursive entropy operator:

$$\mathcal{E}_{n+1} = \mathcal{R}[\mathcal{E}_n],$$

where \mathcal{E}_n is entropy regulation at order n , and \mathcal{R} is the renormalization operator. This makes explicit that culture emerges from mind, mind from life, life from matter, and matter from physics.

4.0.7 Mathematical Summary

Physical order: scalar field conservation, $\nabla \cdot \mathbf{v} = -\frac{\dot{\rho}}{\rho}$.

Material order: vector coherence, stabilized by $\dot{\lambda}$.

Biological order: negentropic limit cycles, locally $\dot{S} < 0$.

Mental order: recursive suppression of entropy by information, $\dot{S} = -\lambda I$.

Cultural order: sheaf cohomology across agents, $H^1(\mathcal{F}) \neq 0$.

Summary

Orders of nature are not metaphysical abstractions but empirically grounded bifurcations in complexity. RSVP provides explicit dynamics for each transition: from scalar conservation to vector coherence, from entropy cycles to recursive cognition, and finally to collective cultural sheaves. The orders of nature thus map onto distinct attractor regimes of the scalar–vector–entropy fields, with each order emerging from yet constraining its predecessors. Complexity thresholds provide the mathematical signature of these emergences, marking the universe as an unfolding hierarchy of probabilistic structures.

Chapter 5

Causality, Teleonomy, and Purpose

Causality has always been the cornerstone of natural philosophy. Aristotle’s fourfold typology—material, formal, efficient, and final causes—remains instructive, even if modern physics initially pared causality down to material and efficient types. Yet the study of complex systems, emergence, and cybernetics requires a rehabilitation of the neglected causes: form (organization) and finality (purpose). Lawrence Cahoon’s naturalism, Peircean fallibilism, and contemporary complexity science converge on a picture where causality is multi-layered, probabilistic, and downwardly constraining. RSVP theory provides explicit equations for these dynamics, grounding Aristotelian categories in field-theoretic form.

5.0.1 Aristotle’s Four Causes in Modern Terms

Aristotle’s schema can be reframed in RSVP fields:

- Material cause: the substrate of a process, captured in RSVP by scalar field density Φ .

$$\text{Material Cause: } M \sim \Phi(x, t).$$

- Formal cause: the organization of matter, expressed in RSVP as vector–scalar coupling:

$$\text{Formal Cause: } F \sim \nabla \Phi \cdot \mathbf{v}.$$

- Efficient cause: the dynamical process producing change, modeled by RSVP advection–diffusion:

$$\dot{\Phi} + \nabla \cdot (\Phi \mathbf{v}) = -\gamma S.$$

- Final cause (Teleology): the end-directed constraint stabilizing processes, formalized in RSVP as attractors minimizing entropy under informational constraints:

$$\lim_{t \rightarrow \infty} (\Phi, \mathbf{v}, S)(t) \rightarrow (\Phi^*, \mathbf{v}^*, S^*).$$

Thus, each cause maps onto RSVP components, yielding a field-theoretic rehabilitation of Aristotelian causality.

5.0.2 Teleonomy and Homeostatic Purpose

To avoid theological overtones, biologists distinguish teleology (purpose imbued by mind) from teleonomy (purposeful-seeming organization arising from natural processes). A thermostat is teleonomic, not teleological. Similarly, life is teleonomic: DNA encodes processes that achieve ends (replication, survival) without invoking foresight.

RSVP models teleonomy as homeostatic attractors:

$$\frac{dS}{dt} = f(\Phi, \mathbf{v}) - \lambda(S - S_0),$$

where S_0 enforces return to a target entropy. Teleonomy thus corresponds to the negative feedback loops stabilizing entropy around viable bounds.

5.0.3 Downward Causation in RSVP

Wimsatt argued that emergent systems exhibit downward causation: higher-level properties constrain lower-level dynamics. RSVP encodes this by modifying vector and scalar evolution via global entropy:

$$\dot{\mathbf{v}} = -\nabla\Phi - \alpha\nabla S + \mu\mathbf{v}_{\text{macro}},$$

where $\mathbf{v}_{\text{macro}}$ is a coarse-grained flow influencing microscopic vectors. This term mathematically represents downward causation: macroscopic order shapes local dynamics.

Example: a biological organism constrains molecular interactions so that proteins fold into functional forms. Without the systemic context, molecules explore vast combinatorial possibilities, but with downward causation, only biologically viable states persist.

5.0.4 Purpose as Attractor Dynamics

Purpose in RSVP arises when entropy gradients and vector flows align to stabilize particular attractors. For instance, the purpose of a heart “pumping blood” is modeled as the persistence of a low-entropy state for the organism relative to its environment.

Formally:

$$\mathcal{P} = \arg \min_{\pi} \mathbb{E}[S_{\text{organism}}(t) | \pi],$$

where π is a policy (structural/behavioral configuration). The “purpose” of a subsystem is the strategy it realizes in minimizing the entropy of the whole.

This definition avoids anthropomorphism while grounding purpose in thermodynamic necessity.

5.0.5 Teleonomy vs Teleology

- Teleonomy: purpose without mind (feedback-regulated entropy minimization).
- Teleology: purpose with mind (representation-based goal pursuit).

In RSVP, both are continuous: teleonomy is low-level entropy regulation, while teleology emerges when recursive entropy modeling allows a system to represent counterfactual states. This is formalized as:

$$\text{Teleology} \iff \exists M : M(\mathcal{S}_t) \mapsto \mathcal{S}_{t+\Delta t},$$

where M is a model used by the system to predict future states. Teleology is teleonomy with simulation capacity.

5.0.6 Cosmological Teleonomy

Even cosmology exhibits teleonomic dynamics when collapsing matter and expanding voids regulate entropy distribution across the universe. Giani et al.’s effective-fluid model of backreaction can be seen as a teleonomic system: voids and clusters act as feedback mechanisms that smooth global expansion. RSVP extends this by interpreting cosmic teleonomy as entropic regulation across scalar–vector–entropy fields:

$$\dot{S}_{\text{cosmos}} \rightarrow \text{stationary equilibrium via clustering and void expansion.}$$

Thus, the universe itself exhibits teleonomy—not in the sense of having a “goal,” but in manifesting persistent, large-scale feedback structures.

5.0.7 Mathematical Models of Teleonomy

Cybernetic Feedback

The canonical cybernetic loop in RSVP:

$$\dot{x}(t) = f(x) - k(x - x_0),$$

with x a field variable, x_0 the target, and k the feedback strength. This formalizes goal-seeking behavior without invoking subjective intention.

Biological Fitness

In evolutionary terms, fitness landscapes correspond to entropy-modulated energy gradients:

$$F(g) = -\nabla S(g) + \eta,$$

where g is genotype and η stochastic mutation noise. Natural selection corresponds to teleonomic pruning of trajectories toward fitness maxima.

Cognitive Purpose

For cognitive systems, purpose manifests as minimizing predictive entropy:

$$\min_{\pi} \mathbb{E}[S_{\text{future}}|\pi],$$

where π is a policy. RSVP-AI treats this as the fundamental definition of agency: the capacity to act in ways that reduce expected entropy.

5.0.8 Complexity, Causality, and Finality

Complexity thresholds (see Section 4) require higher-order causality:

- Material \rightarrow Biological: efficient causes insufficient; teleonomic constraints necessary.
- Biological \rightarrow Mental: recursive downward causation required; informational teleonomy.
- Mental \rightarrow Cultural: distributed teleonomy, encoded as sheaf cohomologies across agents.

Each threshold requires final cause dynamics: attractor-driven constraints directing processes toward end states.

5.0.9 RSVP Summary of Causality

- Material cause: Φ , scalar density.
 - Formal cause: vector structuring, $\nabla\Phi \cdot \mathbf{v}$.
 - Efficient cause: advection–diffusion dynamics.
 - Final cause: attractor convergence, entropy-minimizing trajectories.
- Purpose = convergence to negentropic attractors, formalized in RSVP as:

$$\lim_{t \rightarrow \infty} X(t) \in \mathcal{A}, \quad \mathcal{A} = \arg \min \int S \, dt.$$

Summary

Purpose does not require supernatural teleology. It arises naturally through teleonomy: entropy-regulating feedback systems. Downward causation explains how system-level structures constrain components, and RSVP provides the field equations that formalize this. Teleonomy becomes teleology when systems internalize predictive models. At every scale—from thermostats to hearts, from organisms to galaxies—purpose is the emergent imprint of entropic regulation on dynamics.

Chapter 6

Cosmology's Encoding Ratchet

The cosmological domain exhibits its own encoding ratchet. Just as cinema standardized on 2D frames and computation standardized on ASCII plus von Neumann architecture, cosmology locked itself into the CDM paradigm. While extraordinarily successful, this model reflects a particular encoding of inhomogeneities—treating them as small perturbations on a smooth background rather than as primary nonlinear drivers. Once this encoding took root, scaling (via CMB datasets, N-body simulations, and MCMC parameter fitting) reinforced the ratchet, suppressing alternative formulations such as backreaction or field-theoretic non-expansion models.

6.0.1 CDM as a Chosen Encoding

In the standard model, the large-scale universe is described by the Friedmann–Lemaître–Robertson–Walker (FLRW) metric with constant curvature k , scale factor a , and Hubble parameter $H = \dot{a}/a$. The field equations reduce to the Friedmann equations:

$$3H^2 = 8\pi G\rho + \Lambda - \frac{3k}{a^2}, \quad \dot{H} + H^2 = -\frac{4\pi G}{3}(\rho + 3p) + \frac{\Lambda}{3}.$$

Here, matter is modeled as pressureless dust ($p = 0$) and dark energy as a cosmological constant. Inhomogeneities are inserted perturbatively:

$$g_{\mu\nu} = g_{\mu\nu}^{(0)} + \delta g_{\mu\nu}, \quad \rho = \bar{\rho} + \delta\rho,$$

with the tacit assumption that nonlinear terms average away. This is the ratchet: the encoding assumes smoothness and small perturbations, forcing the cosmological constant to bear explanatory weight for accelerated expansion.

6.0.2 Backreaction and Effective Fluid Reformulation

Alternative encodings—such as the Buchert averaging scheme—treat inhomogeneities not as ignorable perturbations but as sources of effective stress-energy. The scalar-averaged equations introduce kinematical backreaction Q_D and averaged spatial curvature $\langle R \rangle_D$:

$$3\frac{\ddot{a}_D}{a_D} = -4\pi G\langle\rho\rangle_D + Q_D, \quad 3\left(\frac{\dot{a}_D}{a_D}\right)^2 = 8\pi G\langle\rho\rangle_D - \frac{1}{2}\langle R \rangle_D - \frac{1}{2}Q_D.$$

Giani, von Marttens, and Camilleri (2025) re-encode this effect in terms of two effective fluids: collapsing regions (ρ_c) and voids (ρ_v), with effective equations of state w_c , w_v . Their continuity equations are:

$$\dot{\rho}_d + 3H\rho_d = -C(t) - V(t), \quad (6.1)$$

$$\dot{\rho}_c + 3H\rho_c(1 + w_c) = C(t), \quad (6.2)$$

$$\dot{\rho}_v + 3H\rho_v(1 + w_v) = V(t), \quad (6.3)$$

where ρ_d is dust and C, V are couplings. The total energy density is

$$\rho_{\text{tot}} = \rho_d + \rho_c + \rho_v,$$

and the effective equation of state is

$$w_{\text{tot}} = \frac{\rho_c w_c + \rho_v w_v}{\rho_d + \rho_c + \rho_v}. \quad (6.4)$$

Thus, the ratchet is loosened: accelerated expansion emerges not from an imposed cosmological constant but from a re-encoding of nonlinear structure formation.

6.0.3 RSVP Translation

Within the RSVP framework, these effective fluids correspond to structured dynamics of the scalar field Φ , vector flow \mathbf{v} , and entropy density S :

- Collapsing regions correspond to localized negentropic flows ($\nabla \cdot \mathbf{v} < 0$), generating soliton-like scalar concentrations:

$$\dot{\Phi} \sim -\alpha \nabla \cdot \mathbf{v}.$$

- Voids correspond to entropic smoothing regions ($\nabla \cdot \mathbf{v} > 0$), where entropy increases locally:

$$\dot{S} \sim \beta \nabla \cdot \mathbf{v}.$$

The coupling terms C, V are mapped to lamphron–lamphrodyne exchanges, where local constraint relaxation transfers energy between negentropic clumps and entropic voids.

Formally, RSVP defines:

$$\dot{\rho}_\Phi + \nabla \cdot (\rho_\Phi \mathbf{v}) = -\gamma \dot{S}, \quad (6.5)$$

so that entropy gradients source effective energy transfers, analogous to C, V in the effective fluid formalism.

6.0.4 Entropic Reinterpretation of Dark Energy

From the RSVP perspective, what CDM attributes to dark energy is reinterpreted as an entropic redshift effect: cumulative energy loss to the entropy field mimics accelerated expansion. The effective Hubble parameter becomes

$$H_{\text{eff}}(t) = H(t) + \lambda \frac{dS}{dt},$$

where λ is an entropic coupling constant. Observers measuring luminosity distances will then infer a weakening dark energy density, even if total energy is conserved within the plenum.

6.0.5 Ratchet Dynamics in Cosmology

The key philosophical lesson is that cosmology ratcheted into CDM because that encoding scaled computationally: perturbation theory and linearized Boltzmann codes (e.g., CAMB, CLASS) were tractable, while full nonlinear averaging was not. As computing scaled, the ratchet reinforced itself. But as new encodings (effective fluids, RSVP) become feasible, the ratchet may loosen, revealing that what looked like new physics (dark energy) may instead be an artifact of the encoding.

6.0.6 Mathematical Outlook

Future work should quantify the RSVP–effective fluid mapping by:

- Identifying scaling laws:

$$\rho_c \sim a^{-3(1+w_c)}, \quad \rho_v \sim a^{-3(1+w_v)}.$$

- Translating them into RSVP field dynamics:

$$\Phi(t) \sim \Phi_0 e^{-\alpha \int H dt}, \quad S(t) \sim S_0 e^{+\beta \int H dt}.$$

- Testing against DESI/Planck data with alternative ratchets: frame-based CDM, fluid-based backreaction, and plenum-based RSVP.

Summary

Cosmology exemplifies an encoding ratchet: the adoption of CDM encoded the universe as smooth background + perturbations, suppressing nonlinear encodings. Effective fluid models (Giani et al. 2025) show how re-encoding voids and collapsing structures resolves tensions. RSVP pushes further, embedding these effects in scalar–vector–entropy fields, where dark energy becomes an entropic illusion. Just as cinema and computation foreclosed alternative encodings through ratchet effects, cosmology risks mistaking the artifact of an encoding for fundamental physics.

Chapter 7

Natural Religion and the Question of Ground

One of the oldest philosophical questions, preceding even the scientific revolution, concerns the ground of being: what sustains the universe’s existence and coherence at the most fundamental level? Scientific cosmology typically avoids this inquiry, treating the initial conditions of the universe as given. Yet once one admits emergence, causality, and complexity thresholds as real features of nature, the question arises of whether the universe itself participates in a meta-order beyond the physical, material, biological, mental, and cultural.

The aim here is not to import extraneous metaphysics, but to explore whether the RSVP framework—by unifying entropy, vector flows, and scalar densities—can illuminate the possibility of a grounding order implicit in natural processes.

7.0.1 Contingency and Necessity

Modern physics suggests two possible explanatory regimes for why the universe is as it is:

- Contingency hypothesis: The constants and laws of physics are contingent outcomes of a larger ensemble of possibilities (multiverse, eternal inflation, string landscapes). Our universe is one realization among many.

- Necessity hypothesis: The universe’s parameters are uniquely constrained by deeper principles. The laws of physics and their constants are not accidental but follow from the structure of the ground itself.

RSVP does not presuppose either view, but it reframes the problem: constants and initial conditions can be treated as scalar–vector–entropy boundary conditions. Whether they are contingent or necessary depends on whether the plenum itself is stochastic (ensemble-based) or self-normalizing (necessity-based).

Mathematically, this corresponds to whether the scalar field boundary is drawn from a distribution (contingency) or fixed by variational constraints:

$$\delta \int \mathcal{L}(\Phi, \mathbf{v}, S) d^4x = 0$$

(necessity).

7.0.2 Fine-Tuning and Emergence

A long-standing puzzle is the fine-tuning of constants: slight variations in the electron-to-proton mass ratio, the cosmological constant, or the strength of gravity would preclude stable stars, chemistry, or life. Standard cosmology treats this as coincidence or invokes anthropic reasoning.

RSVP provides an alternative: fine-tuning may be a secondary effect of entropy–vector feedback. If the plenum operates to minimize long-term instability, then constants are not freely chosen but emerge as fixed points of the entropy–field equations. For example:

$$\frac{\partial \Phi}{\partial t} = f(\Phi, \mathbf{v}, S), \quad \lim_{t \rightarrow \infty} \Phi(t) = \Phi^*,$$

with Φ^* a stable constant attractor. Fine-tuning, in this picture, is not improbable coincidence but the natural consequence of attractor dynamics.

7.0.3 Hazard, Disorder, and Contingency

Even if attractors explain stability, RSVP admits the second law of entropy as irreducible. The plenum is filled with hazard and disorder. Collapse, extinction, and catastrophe are not aberrations but intrinsic features. The “ground” of being, therefore, cannot be imagined as wholly ordered; it must incorporate probabilistic variation, fluctuation, and instability.

This view resonates with objective relativism: entities are never independent but always conditioned by relations. The ground is not a static substrate but a field of relations in perpetual transformation. Thus, to ask “why something rather than nothing” is to ask about the recursive stability of relation itself.

7.0.4 Emergence of Ground as Meta-Order

If the physical, material, biological, mental, and cultural are successive orders, is there an overarching meta-order—the condition that allows orders to emerge at all?

RSVP suggests that such a ground exists in the recursive closure of entropy and negentropy. The entire cascade of orders rests on the capacity of entropy gradients to generate local negentropic flows. This recursive alternation of dissipation and stabilization may itself be the “ground of order.”

Formally:

$$\text{Ground}(t) = \Phi(t) + \mathbf{v}(t) + S(t), \quad \text{with } \frac{d}{dt}\text{Ground}(t) = 0.$$

Here, “ground” means not an external cause but the conserved relation of scalar, vector, and entropy components across all transformations.

7.0.5 Natural Religion Without Supernaturalism

A natural religion—if the term may be cautiously retained—does not posit a transcendent deity or supernatural force. Instead, it recognizes in the plenum a source of awe and orientation. To reflect on the fact that entropy, vector flows, and scalar fields generate stars, life, mind, and culture is to see that the universe has within it a recursive generativity sufficient to sustain meaning.

Purpose, in this framework, is not imposed from outside but is the emergent convergence toward entropy-regulating attractors. If there is reverence to be found, it is not for something external to nature but for the capacity of nature itself to organize complexity against disorder.

7.0.6 Mathematical Appendix: Ground Formalization

Let the RSVP system evolve on a manifold M :

$$\mathcal{L} = \frac{1}{2}|\nabla\Phi|^2 + \frac{1}{2}|\mathbf{v}|^2 - \sigma S.$$

Define the ground functional:

$$G = \int_M (\Phi + \mathbf{v} + S) d^3x.$$

If $\dot{G} = 0$, then the ground is conserved across all emergent orders. This condition does not explain why the universe exists but formalizes how persistence is possible: relational invariance across scales.

Summary

The ground of being, in RSVP terms, is the conserved relational structure of scalar density, vector flows, and entropy dynamics. Fine-tuning may reflect attractor stability rather than chance. Hazard and disorder are intrinsic, not anomalies. The meta-order is recursive entropic regulation, from which all orders of nature cascade. What has been called “religion” in this context is simply reverence for this generative ground—a recognition that purpose and meaning are emergent within nature itself.

Chapter 8

Complexity and Orders of Nature

The study of emergence requires a framework for distinguishing levels of organization in nature. Lawrence Cahoon proposes five orders of nature—physical, material, biological, mental, and cultural—each corresponding to a domain where complexity reaches a threshold such that new causal structures appear. These orders are neither arbitrary nor merely anthropocentric. They align with the disciplinary divisions of science, the history of cosmic evolution, and the mathematics of complexity thresholds. RSVP, by embedding scalar density (Φ), vector flow (\mathbf{v}), and entropy (S) fields, provides a unified framework in which these orders can be expressed as regimes of scalar–vector–entropy coupling.

8.0.1 The Five Orders in RSVP Terms

1. Physical Order

The domain of energy, spacetime, and field interactions.

RSVP fields reduce here to scalar–vector equations without biological or cognitive constraints:

$$\dot{\Phi} = -\nabla \cdot (\Phi \mathbf{v}).$$

2. Material Order

The domain of stable compounds, crystals, and reactive networks.

RSVP extension: entropy regulation becomes non-trivial, yielding bounded attractors:

$$\dot{S} = f(\Phi, \mathbf{v}) - \lambda(S - S_0).$$

3. Biological Order

Autopoietic systems maintain low entropy via recursive regulation. Teleonomy emerges:

$$\frac{d}{dt}\Phi_{\text{org}} = -\nabla \cdot (\Phi_{\text{org}} \mathbf{v}) + \beta(\Phi_{\text{org}} - \Phi^*),$$

4. Mental Order

Recursive feedback enables prediction and action selection. RSVP maps this onto entropy minimization in policy space:

$$\pi^* = \arg \min_{\pi} \mathbb{E}[S_{\text{future}} | \pi].$$

5. Cultural Order

Information is stored and transmitted collectively. RSVP interprets this as meta-fields:

$$\mathcal{C}_{\text{cultural}} = \bigcup_i \mathcal{C}_{\text{mental},i} \text{ coupled via shared entropy fields } S_{\text{shared}}.$$

8.0.2 Complexity as Scale-Relative

A system's complexity is not an absolute property but depends on the scale of observation. At different scales, different variables dominate, different couplings are relevant, and different forms of entropy regulation occur. RSVP formalizes this through scale-dependent entropy:

$$S(\ell, \tau) = - \sum_{x \in \mathcal{X}(\ell, \tau)} P(x) \ln P(x),$$

where ℓ and τ are spatial and temporal coarse-graining parameters. Complexity arises when entropy does not monotonically increase under rescaling but exhibits local minima (organization) and maxima (chaos).

8.0.3 Characteristic Scales

Each natural order (physical, material, biological, mental, cultural) is marked by characteristic time scales and length scales. For example:

- Physics: particle interactions (10^{-43} s)
- Chemistry: molecular vibrations (10^{-12} s)
- Biology: metabolic cycles (10^{-3} s)
- Neuroscience: neural spikes (10^{-3} s)
- Culture: linguistic conventions, economic cycles (10^3 s)

Emergence occurs when processes at one time scale entrain or constrain processes at another. RSVP encodes this via multi-scale coupling:

$$\dot{x}_i(\tau) = f(x_i) + \sum_{\tau' \neq \tau} \kappa_{\tau\tau'} g(x_{\tau'}, x_{\tau}),$$

where $\kappa_{\tau\tau'}$ measures cross-scale coupling strength.

8.0.4 Complexity as Multi-Scale Entropy Gradient

RSVP frames emergence as the interplay between entropy production at different scales:

$$\frac{dS}{dt} = \sum_{\tau} \sigma(\tau),$$

with $\sigma(\tau)$ the entropy production rate at scale τ . A system is complex if no single $\sigma(\tau)$ dominates; instead, several scales interact nonlinearly to maintain stability. For example, the human brain maintains coherence by balancing millisecond-level spike trains with second-level oscillations and years-long learning.

8.0.5 Downward Causation as Cross-Scale Constraint

Downward causation, central to Cahoon's account, can be expressed as cross-scale entropy regulation:

$$\sigma(\tau_{\text{lower}}) \rightarrow f(\sigma(\tau_{\text{higher}})).$$

For instance, in organisms, long-term genetic regulation (slow scale) constrains fast molecular dynamics (fast scale). Similarly, cultural norms (slow, high-level scale) constrain individual decisions (fast, low-level scale).

RSVP treats downward causation as a renormalization constraint:

$$\mathcal{R}[\Phi(\ell), \mathbf{v}(\ell), S(\ell)] = \Phi(\ell'), \mathbf{v}(\ell'), S(\ell'),$$

where $\ell' > \ell$. Higher-level organization corresponds to fixed points of the renormalization operator \mathcal{R} .

8.0.6 Complexity Measures in RSVP

We can define a complexity index for an RSVP system by quantifying cross-scale coupling:

$$\mathcal{C} = \sum_{\tau < \tau'} |\kappa_{\tau\tau'}| I(X_\tau; X_{\tau'}),$$

where I is the mutual information between states at two scales. A system is maximally complex when many scales share strong mutual information, as in biological and cultural systems.

8.0.7 Cross-Scale Entropic Resonance

A novel RSVP prediction is entropic resonance, where fluctuations at one scale entrain stability at another. Formally:

$$R(\ell_1, \ell_2) = \frac{I(S_{\ell_1}; \Phi_{\ell_2}, \mathbf{v}_{\ell_2})}{H(S_{\ell_1})}.$$

If $R > 0.5$, then over half the entropy at scale ℓ_1 is constrained by higher-level structure at ℓ_2 . This mathematically encodes the idea that emergent wholes constrain their parts.

8.0.8 Time as an Emergent Order Parameter

In RSVP, time itself can be reinterpreted not as an external parameter but as an emergent ordering variable defined by entropy gradients:

$$t \sim \int \frac{dS}{\sigma_{\text{eff}}},$$

where σ_{eff} is the effective entropy production across scales. This suggests that “time” is fundamentally tied to multi-scale entropic unfolding, rather than a primitive background variable. This resonates with both Prigogine's arrow of time and Cahoon's emphasis on fallibilist local metaphysics: time is real, but only locally structured by the dynamics of entropy production.

Summary

Complexity, in both Cahoone's and RSVP's frameworks, is not an abstract property but a function of scale and time. Emergence corresponds to nonaggregative behavior across characteristic scales; downward causation corresponds to cross-scale entropy constraints; and complexity is measurable via cross-scale mutual information. RSVP thereby provides a quantitative foundation for Cahoone's qualitative insight: we live in the middle, where multi-scale entropic dynamics create the richness of the natural world.

Chapter 9

Orders of Nature and Complexity Thresholds

The concept of orders of nature provides a structured lens through which to view emergence. Lawrence Cahoon, drawing from Justus Buchler’s “natural complexes” and William Wimsatt’s work on complexity, identifies at least five robust orders: physical, material, biological, mental, and cultural. Each order is characterized by distinctive processes, structures, and scaling laws, and each is emergent from yet constraining upon the lower orders.

In RSVP (Relativistic Scalar–Vector Plenum), these orders correspond to successive bifurcations in the scalar–vector–entropy field dynamics. Complexity thresholds, marked by sharp changes in scaling behavior, delineate the transitions between orders. Thus, orders of nature can be formalized as distinct regimes of RSVP equations.

9.0.1 The Five Orders in RSVP Terms

1. Physical Order

The domain of energy, spacetime, and field interactions.

RSVP fields reduce here to scalar–vector equations without biological or cognitive constraints:

$$\dot{\Phi} = -\nabla \cdot (\Phi \mathbf{v}).$$

2. Material Order

The domain of stable compounds, crystals, and reactive networks.

RSVP extension: entropy regulation becomes non-trivial, yielding bounded attractors:

$$\dot{S} = f(\Phi, \mathbf{v}) - \lambda(S - S_0).$$

3. Biological Order

Autopoietic systems maintain low entropy via recursive regulation. Teleonomy emerges:

$$\frac{d}{dt}\Phi_{\text{org}} = -\nabla \cdot (\Phi_{\text{org}} \mathbf{v}) + \beta(\Phi_{\text{org}} - \Phi^*),$$

4. Mental Order

Recursive feedback enables prediction and action selection. RSVP maps this onto entropy minimization in policy space:

$$\pi^* = \arg \min_{\pi} \mathbb{E}[S_{\text{future}}|\pi].$$

5. Cultural Order

Information is stored and transmitted collectively. RSVP interprets this as meta-fields:

$$\mathcal{C}_{\text{cultural}} = \bigcup_i \mathcal{C}_{\text{mental},i} \text{ coupled via shared entropy fields } S_{\text{shared}}.$$

9.0.2 Complexity as Scale-Relative

A system's complexity is not an absolute property but depends on the scale of observation. At different scales, different variables dominate, different couplings are relevant, and different forms of entropy regulation occur. RSVP formalizes this through scale-dependent entropy:

$$S(\ell, \tau) = - \sum_{x \in \mathcal{X}(\ell, \tau)} P(x) \ln P(x),$$

where ℓ and τ are spatial and temporal coarse-graining parameters. Complexity arises when entropy does not monotonically increase under rescaling but exhibits local minima (organization) and maxima (chaos).

9.0.3 Characteristic Scales

Each natural order (physical, material, biological, mental, cultural) is marked by characteristic time scales and length scales. For example:

- Physics: particle interactions (10^{-43} s)
- Chemistry: molecular vibrations (10^{-12} s)
- Biology: metabolic cycles (10^{-3} s)
- Neuroscience: neural spikes (10^{-3} s)
- Culture: linguistic conventions, economic cycles (10^3 s)

Emergence occurs when processes at one time scale entrain or constrain processes at another. RSVP encodes this via multi-scale coupling:

$$\dot{x}_i(\tau) = f(x_i) + \sum_{\tau' \neq \tau} \kappa_{\tau\tau'} g(x_{\tau'}, x_{\tau}),$$

where $\kappa_{\tau\tau'}$ measures cross-scale coupling strength.

9.0.4 Complexity as Multi-Scale Entropy Gradient

RSVP frames emergence as the interplay between entropy production at different scales:

$$\frac{dS}{dt} = \sum_{\tau} \sigma(\tau),$$

with $\sigma(\tau)$ the entropy production rate at scale τ . A system is complex if no single $\sigma(\tau)$ dominates; instead, several scales interact nonlinearly to maintain stability. For example, the human brain maintains coherence by balancing millisecond-level spike trains with second-level oscillations and years-long learning.

9.0.5 Downward Causation as Cross-Scale Constraint

Downward causation, central to Cahoon's account, can be expressed as cross-scale entropy regulation:

$$\sigma(\tau_{\text{lower}}) \rightarrow f(\sigma(\tau_{\text{higher}})).$$

For instance, in organisms, long-term genetic regulation (slow scale) constrains fast molecular dynamics (fast scale). Similarly, cultural norms (slow, high-level scale) constrain individual decisions (fast, low-level scale).

RSVP treats downward causation as a renormalization constraint:

$$\mathcal{R}[\Phi(\ell), \mathbf{v}(\ell), S(\ell)] = \Phi(\ell'), \mathbf{v}(\ell'), S(\ell'),$$

where $\ell' > \ell$. Higher-level organization corresponds to fixed points of the renormalization operator \mathcal{R} .

9.0.6 Complexity Measures in RSVP

We can define a complexity index for an RSVP system by quantifying cross-scale coupling:

$$\mathcal{C} = \sum_{\tau < \tau'} |\kappa_{\tau\tau'}| I(X_\tau; X_{\tau'}),$$

where I is the mutual information between states at two scales. A system is maximally complex when many scales share strong mutual information, as in biological and cultural systems.

9.0.7 Cross-Scale Entropic Resonance

A novel RSVP prediction is entropic resonance, where fluctuations at one scale entrain stability at another. Formally:

$$R(\ell_1, \ell_2) = \frac{I(S_{\ell_1}; \Phi_{\ell_2}, \mathbf{v}_{\ell_2})}{H(S_{\ell_1})}.$$

If $R > 0.5$, then over half the entropy at scale ℓ_1 is constrained by higher-level structure at ℓ_2 . This mathematically encodes the idea that emergent wholes constrain their parts.

9.0.8 Time as an Emergent Order Parameter

In RSVP, time itself can be reinterpreted not as an external parameter but as an emergent ordering variable defined by entropy gradients:

$$t \sim \int \frac{dS}{\sigma_{\text{eff}}},$$

where σ_{eff} is the effective entropy production across scales. This suggests that “time” is fundamentally tied to multi-scale entropic unfolding, rather than a primitive background variable. This resonates with both Prigogine's arrow of time and Cahoon's emphasis on fallibilist local metaphysics: time is real, but only locally structured by the dynamics of entropy production.

Summary

Complexity, in both Cahoone's and RSVP's frameworks, is not an abstract property but a function of scale and time. Emergence corresponds to nonaggregative behavior across characteristic scales; downward causation corresponds to cross-scale entropy constraints; and complexity is measurable via cross-scale mutual information. RSVP thereby provides a quantitative foundation for Cahoone's qualitative insight: we live in the middle, where multi-scale entropic dynamics create the richness of the natural world.

Chapter 10

Knowledge, Fallibilism, and Natural Epistemics

If heuristics, rules, and laws describe the continuum of stability in natural systems, then the epistemic corollary is fallibilism: the recognition that knowledge is never final, but always partial, local, and open to revision. Cahoon frames this in terms of objective relativism: no entity exists in isolation; every complex is defined by its relations. From this perspective, metaphysics must remain “local,” since there is no ultimate vantage point from which “the whole” can be surveyed. RSVP theory both endorses and extends this view, formalizing it as a property of field dynamics: knowledge is always constrained by entropy and scale, and inquiry is the recursive attempt to reduce uncertainty across shifting contexts.

10.0.1 Peircean Fallibilism

Peirce insisted that all human knowledge is provisional. Even the most successful scientific laws are subject to refinement or replacement when anomalies accumulate. This is not a weakness but a structural condition of inquiry: progress occurs not by certainties but by converging approximations.

In RSVP, this is modeled as a Bayesian updating process over entropy fields. Let \mathcal{H}_t denote the hypothesis state at time t . Then:

$$P(\mathcal{H}_{t+1}|D_t) \propto P(D_t|\mathcal{H}_t) P(\mathcal{H}_t),$$

where D_t are new observations. Fallibilism arises because no finite dataset D can ever collapse uncertainty to zero; entropy remains bounded below by:

$$S_{\text{knowledge}} \geq S_{\text{min}} > 0.$$

Thus, even “laws” are best understood as attractors toward which knowledge asymptotically converges.

10.0.2 Objective Relativism and Contextual Ontology

The Columbian naturalists argued for objective relativism: entities are never absolute simples but always complexes, whose identity is determined by relations. For example, an electron cannot be defined without reference to the electromagnetic field in which it

exists. Likewise, cultural practices are not intrinsic but relational, embedded in history, geography, and institutions.

RSVP provides a mathematical ontology of this claim. Each entity is described as a triple:

$$\mathcal{C} = (\Phi, \mathbf{v}, S),$$

and its properties are functions of its relations to other complexes:

$$\mathcal{R}(\mathcal{C}_i, \mathcal{C}_j) = f(\Phi_i, \Phi_j, \mathbf{v}_i, \mathbf{v}_j, S_i, S_j).$$

No \mathcal{C} exists in isolation; its reality is given by its entropic and vectorial embedding. Objective relativism is thus not just a philosophical stance but a structural property of RSVP fields.

10.0.3 Natural Complexes

Justus Buchler proposed that reality is composed of natural complexes: anything discriminable—objects, processes, possibilities, meanings—is a complex. His principle of ontological parity states that no complex is more or less real than any other. A rock, a dream, and an equation are all real in their respective orders of relation.

RSVP reinterprets natural complexes as field configurations. Each complex corresponds to a region of plenum with characteristic scalar density, vector flow, and entropy. Ontological parity is mathematically expressed as:

$$\forall \mathcal{C}_i, \quad \exists (\Phi_i, \mathbf{v}_i, S_i) \neq \emptyset.$$

Thus, the reality of a complex is its capacity to be represented in the plenum fields, regardless of its scale or category.

10.0.4 Epistemics as Entropy Reduction

Knowledge is the structured reduction of entropy about complexes. RSVP frames epistemics as an inverse problem: given partial observations of (Φ, \mathbf{v}, S) , infer the underlying configuration. This aligns with both Bayesian inference and the free energy principle:

$$F = \mathbb{E}_q[\ln q(\mathcal{C}) - \ln P(\mathcal{C}, D)],$$

minimized when our model q best approximates the true distribution P . Knowledge, then, is neither absolute nor illusory; it is the ongoing minimization of informational entropy under structural constraints.

10.0.5 Local Metaphysics

Cahoone’s term local metaphysics encapsulates this approach: metaphysics should not seek “the Whole” but instead articulate how complexes hang together in particular contexts. RSVP embodies this locality mathematically: entropy fields ensure that no observation can span the entire plenum without distortion. Knowledge is always fractal and scale-dependent, defined by tilings and patches rather than a single global chart. This is why RSVP deploys tools like sheaf theory: to describe how local knowledge patches glue together consistently.

Summary

Knowledge is not certainty but fallible approximation. Entities are not simples but relational complexes. Inquiry is not the discovery of foundations but the recursive reduction of entropy across contexts. RSVP translates these philosophical commitments into field-theoretic and information-theoretic terms: knowledge is Bayesian updating over entropy fields, natural complexes are scalar–vector–entropy triples, and local metaphysics is enforced by the fractal structure of the plenum. Fallibilism thus becomes not a limitation but the essential condition of progress.

Chapter 11

Teleonomy, Purpose, and Downward Causation

The emergence of purpose has long been a central tension in philosophy and science. Aristotle distinguished between four causes—material, formal, efficient, and final—yet modern physics largely reduced causation to efficient processes in matter. Cahoon, following Mayr and Monod, reintroduces teleonomy: goal-directedness without mind. RSVP theory provides a natural framework for uniting teleonomy, downward causation, and emergent purpose.

11.0.1 Aristotle’s Four Causes in Modern Terms

Aristotle’s schema can be reframed in RSVP fields:

- Material cause: scalar density Φ , the “stuff” of a system.

$$\text{Material Cause: } M \sim \Phi(x, t).$$

- Formal cause: structural configuration, encoded in $\nabla\Phi \cdot \mathbf{v}$.

$$\text{Formal Cause: } F \sim \nabla\Phi \cdot \mathbf{v}.$$

- Efficient cause: vector flows \mathbf{v} , driving change.

$$\dot{\Phi} + \nabla \cdot (\Phi \mathbf{v}) = -\gamma S.$$

- Final cause: emergent constraints imposed by entropy gradients S , directing systems toward particular attractors.

$$\lim_{t \rightarrow \infty} (\Phi, \mathbf{v}, S)(t) \rightarrow (\Phi^*, \mathbf{v}^*, S^*).$$

Thus, final causes need not be supernatural teleology; they emerge when higher-level structures constrain the dynamics of components.

11.0.2 Teleonomy: Goal-Directed Systems Without Mind

Colin Pittendrigh and Ernst Mayr introduced teleonomy to describe systems that appear purposeful because they regulate deviations from a target state. A thermostat maintains temperature; an organism maintains homeostasis. These are not illusions of purpose but real cybernetic architectures.

RSVP models teleonomy as negative entropy feedback:

$$\dot{S}(t) = -\kappa(S(t) - S^*),$$

where S^* is the target entropy (e.g., homeostatic equilibrium), and κ is the rate of correction.

Teleonomic systems are thus entropic regulators embedded in larger fields.

11.0.3 Downward Causation

A defining feature of emergence is downward causation: the system-level organization constrains component behavior. For example, in an organism, the heart’s function is not explained by its cells alone; its role in circulation constrains cellular activity.

In RSVP, downward causation is represented by cross-scale coupling terms:

$$\dot{x}_i = f(x_i) + g(\mathcal{S}),$$

where x_i is a component’s state, f is its intrinsic dynamics, and \mathcal{S} encodes influence from system-level structure.

This formalizes Harold Morowitz’s intuition that higher-level structures act as pruning rules: they don’t micromanage components, but they restrict possible trajectories, narrowing entropy growth into functional channels.

11.0.4 Purpose as Emergent Constraint

Purpose in RSVP arises when entropy gradients and vector flows align to stabilize particular attractors. For instance, the purpose of a heart “pumping blood” is modeled as the persistence of a low-entropy state for the organism relative to its environment.

Formally:

$$\mathcal{P} = \arg \min_{\pi} \mathbb{E}[S_{\text{organism}}(t) | \pi],$$

where π is a policy (structural/behavioral configuration). The “purpose” of a subsystem is the strategy it realizes in minimizing the entropy of the whole.

This definition avoids anthropomorphism while grounding purpose in thermodynamic necessity.

11.0.5 Teleonomy vs Teleology

- Teleonomy: purpose without mind (feedback-regulated entropy minimization).
- Teleology: purpose with mind (representation-based goal pursuit).

In RSVP, both are continuous: teleonomy is low-level entropy regulation, while teleology emerges when recursive entropy modeling allows a system to represent counterfactual states. This is formalized as:

$$\text{Teleology} \iff \exists M : M(\mathcal{S}_t) \mapsto \mathcal{S}_{t+\Delta t},$$

where M is a model used by the system to predict future states. Teleology is teleonomy with simulation capacity.

11.0.6 Cosmological Teleonomy

Even cosmology exhibits teleonomic dynamics when collapsing matter and expanding voids regulate entropy distribution across the universe. Giani et al.’s effective-fluid model of backreaction can be seen as a teleonomic system: voids and clusters act as feedback mechanisms that smooth global expansion. RSVP extends this by interpreting cosmic teleonomy as entropic regulation across scalar–vector–entropy fields:

$$\dot{S}_{\text{cosmos}} \rightarrow \text{stationary equilibrium via clustering and void expansion.}$$

Thus, the universe itself exhibits teleonomy—not in the sense of having a “goal,” but in manifesting persistent, large-scale feedback structures.

11.0.7 Mathematical Models of Teleonomy

Cybernetic Feedback

The canonical cybernetic loop in RSVP:

$$\dot{x}(t) = f(x) - k(x - x_0),$$

with x a field variable, x_0 the target, and k the feedback strength. This formalizes goal-seeking behavior without invoking subjective intention.

Biological Fitness

In evolutionary terms, fitness landscapes correspond to entropy-modulated energy gradients:

$$F(g) = -\nabla S(g) + \eta,$$

where g is genotype and η stochastic mutation noise. Natural selection corresponds to teleonomic pruning of trajectories toward fitness maxima.

Cognitive Purpose

For cognitive systems, purpose manifests as minimizing predictive entropy:

$$\min_{\pi} \mathbb{E}[S_{\text{future}}|\pi],$$

where π is a policy. RSVP-AI treats this as the fundamental definition of agency: the capacity to act in ways that reduce expected entropy.

11.0.8 Complexity, Causality, and Finality

Complexity thresholds (see Section 4) require higher-order causality:

- Material \rightarrow Biological: efficient causes insufficient; teleonomic constraints necessary.
- Biological \rightarrow Mental: recursive downward causation required; informational teleonomy.
- Mental \rightarrow Cultural: distributed teleonomy, encoded as sheaf cohomologies across agents.

Each threshold requires final cause dynamics: attractor-driven constraints directing processes toward end states.

11.0.9 RSVP Summary of Causality

- Material cause: Φ , scalar density.
 - Formal cause: vector structuring, $\nabla\Phi \cdot \mathbf{v}$.
 - Efficient cause: advection–diffusion dynamics.
 - Final cause: attractor convergence, entropy-minimizing trajectories.
- Purpose = convergence to negentropic attractors, formalized in RSVP as:

$$\lim_{t \rightarrow \infty} X(t) \in \mathcal{A}, \quad \mathcal{A} = \arg \min \int S \, dt.$$

Summary

Purpose does not require supernatural teleology. It arises naturally through teleonomy: entropy-regulating feedback systems. Downward causation explains how system-level structures constrain components, and RSVP provides the field equations that formalize this. Teleonomy becomes teleology when systems internalize predictive models. At every scale—from thermostats to hearts, from organisms to galaxies—purpose is the emergent imprint of entropic regulation on dynamics.

Chapter 12

Integration with Cosmological Backreaction

Cahoone’s pluralistic metaphysics, particularly his recognition that emergence is ubiquitous and layered, resonates strongly with recent cosmological work such as the effective fluid model of Giani, von Marttens, and Camilleri. RSVP theory provides a natural mathematical bridge: both approaches see large-scale structures (voids, clusters, filaments) as contributing backreaction effects that alter the effective dynamics of the cosmos.

12.0.1 Backreaction in Standard Cosmology

In the CDM model, the Universe is described on large scales by the Friedmann–Lemaître–Robertson–Walker (FLRW) metric, which assumes homogeneity and isotropy. Small-scale inhomogeneities are “averaged out.” However, the Buchert formalism shows that inhomogeneities generate correction terms:

$$3\frac{\ddot{a}}{a} = -4\pi G\langle\rho\rangle + Q,$$
$$3\left(\frac{\dot{a}}{a}\right)^2 = 8\pi G\langle\rho\rangle - \frac{1}{2}\langle R\rangle - \frac{1}{2}Q,$$

where Q is the kinematical backreaction and $\langle R\rangle$ is the averaged spatial curvature.

12.0.2 Giani–von Marttens Effective Fluids

Instead of directly averaging Einstein’s equations, Giani et al. model non-linear inhomogeneities (clusters and voids) as effective fluids with their own equations of state:

$$\dot{\rho}_c + 3H\rho_c(1 + w_c) = C(t),$$

$$\dot{\rho}_v + 3H\rho_v(1 + w_v) = V(t),$$

where ρ_c, ρ_v represent clustered and void contributions, and C, V describe coupling to dust. The total effective equation of state becomes:

$$w_{\text{tot}} = \frac{\rho_c w_c + \rho_v w_v}{\rho_d + \rho_c + \rho_v}.$$

This structure reproduces Buchert’s Q and $\langle R\rangle$ terms in an effective-fluid form.

12.0.3 RSVP Integration: Entropy–Vector–Scalar Fields

RSVP interprets these backreaction fluids not as phenomenological stand-ins, but as manifestations of scalar (Φ), vector (\mathbf{v}), and entropy (S) fields. For example:

- Collapsing regions (clusters) \rightarrow local minima in Φ , high vorticity in \mathbf{v} .
- Expanding voids \rightarrow Φ deficits, negative pressure, entropy release.

Coupling terms $C, V \rightarrow$ fluxes in entropy:

$$\dot{S} = \int (\nabla \cdot \mathbf{v}) dV,$$

which redistribute entropy between regions.

Thus, the Giani effective fluids correspond to mesoscale RSVP field configurations averaged over characteristic scales.

12.0.4 Entropic Redshift as Apparent Expansion

In RSVP, redshift is not evidence of metric expansion but of cumulative entropy smoothing along photon trajectories. Backreaction terms then appear as scale-dependent entropy corrections:

$$z_{\text{eff}}(d) = \int_0^d \frac{\sigma_S(\ell)}{c} d\ell,$$

where σ_S is the entropy production density along the path. This reproduces backreaction effects without invoking global expansion.

12.0.5 Resolution of Hubble and 8 Tensions

The effective-fluid approach shows that inhomogeneities can reconcile the early- and late-universe discrepancies in H_0 and σ_8 . RSVP strengthens this:

- H_0 tension resolves because entropy flux in voids alters distance–redshift relations.
- σ_8 tension resolves because vector flows redistribute density contrasts via entropic relaxation.

Formally:

$$\sigma_8^{\text{eff}} = \sigma_8^{\Lambda\text{CDM}} - \int \kappa(\ell) S(\ell) d\ell,$$

where κ is the entropy–density coupling kernel.

12.0.6 Philosophical Integration

Cahoone’s local metaphysics aligns with this cosmological picture:

- There is no “one true” homogeneous universe, only local effective descriptions.
- Orders of nature (physical, material, biological, mental, cultural) arise from recursive entropy regulation, just as cosmic backreaction arises from recursive averaging of structures.
- Both invite a fallibilist epistemology: our cosmology is local, provisional, and context-dependent.

Summary

By integrating RSVP’s entropy fields with the Giani–von Marttens effective fluid approach, we can interpret cosmological backreaction not merely as an adjustment to

CDM but as evidence that entropy-regulating emergence is foundational to the Universe's large-scale structure. Just as Cahoon emphasizes that metaphysics is local and emergent, RSVP demonstrates that cosmology itself is a layered, entropy-driven phenomenon rather than a monolithic expansion.

Chapter 13

Comparative Frameworks of Emergence: Wimsatt, Morowitz, Hoel vs RSVP

Emergence has been conceptualized differently across philosophy, biology, complexity science, and physics. While all agree that novel properties arise at higher levels of organization, they differ on why and how. In this section we map three influential frameworks—Wimsatt’s aggregativity criteria, Morowitz’s ladder of emergence, and Hoel’s causal emergence—onto RSVP’s scalar–vector–entropy fields. This establishes RSVP not as a competing metaphor, but as a mathematically explicit unifying theory of emergence.

13.0.1 Wimsatt: Emergence as Non-Aggregativity

Wimsatt defined emergence not mystically but pragmatically: a property is emergent if it is non-aggregative, meaning it cannot be derived by simple addition of parts. His criteria included:

1. Failure of summation
2. Non-linear interdependence
3. Context-dependence of components

Mathematically, for a system with components x_i :

$$P_{\text{system}} \neq \sum_i P(x_i),$$

but instead

$$P_{\text{system}} = f(\{x_i\}, \text{relations}),$$

where f is non-linear.

RSVP naturally encodes this: the vector field \mathbf{v} couples components through non-linear terms like $\Phi \nabla \cdot \mathbf{v}$, producing emergent vortices, attractors, and instabilities.

13.0.2 Morowitz: The Emergence of Everything

Morowitz catalogued 28 thresholds of emergence, from baryogenesis to culture. His key insight was that life and complexity arise at discrete jumps in entropy gradients. Each new level introduces new conservation laws and pruning rules.

Formally, let entropy production at level n be σ_n . Morowitz's ladder posits:

$$\sigma_{n+1} = \sigma_n - \Delta\sigma,$$

where $\Delta\sigma$ is exported entropy that allows local order to stabilize.

RSVP sharpens this picture by showing that $\Delta\sigma$ corresponds to fluxes in the entropy field S :

$$\frac{dS}{dt} = \nabla \cdot \mathbf{J}_S,$$

where \mathbf{J}_S is the entropy flux vector. Thus, Morowitz's steps are RSVP's phase boundaries in entropy space.

13.0.3 Hoel: Causal Emergence

Hoel argued that emergence should be defined not by ontological novelty but by causal power at higher levels. In information-theoretic terms, a coarse-grained system can have more effective information (EI) than its microscopic substrate:

$$EI = I(\text{macro causes; macro effects}) > I(\text{micro causes; micro effects}).$$

This provides a measurable sense of downward causation.

RSVP generalizes this by defining entropy-constrained mutual information:

$$EI_{\text{RSVP}} = I(\Phi, \mathbf{v}; S) - \lambda H(S|\Phi, \mathbf{v}),$$

where λ weights entropy penalties. Thus, emergent causal power is tied to the ability of higher-level fields to prune entropy pathways, resonating with Jim Rutt's "pruning rules" and with RSVP's lamphron-lamphrodyne dynamics.

13.0.4 RSVP: Emergence as Entropy-Vector Coupling

Unlike Wimsatt (structure), Morowitz (history), or Hoel (causality), RSVP defines emergence dynamically:

$$\mathcal{E} = \int \Phi \nabla \cdot \mathbf{v} dV - \int S \dot{\Phi} dV.$$

Here, \mathcal{E} quantifies emergence as the cross-coupling of scalar potential, vector flow, and entropy smoothing. A property is emergent if $\mathcal{E} > 0$, i.e., if field interactions create new, entropy-regulating structures not predictable from linear components.

13.0.5 Comparative Summary

- Wimsatt: emergence = non-aggregativity \rightarrow RSVP: non-linear field couplings.
 - Morowitz: emergence = entropy thresholds \rightarrow RSVP: phase boundaries in entropy flux.
 - Hoel: emergence = causal power \rightarrow RSVP: entropy-constrained mutual information.
- RSVP subsumes all three by giving a continuous mathematical basis for emergence as entropy-regulating vector-scalar field interactions.

Summary

By mapping Wimsatt, Morowitz, and Hoel into RSVP, we find that what appear as competing philosophies of emergence are actually complementary slices of a single phenomenon. RSVP provides the formal grammar through which these insights can be unified and extended into cosmology, cognition, and culture.

Chapter 14

Heuristics, Laws, and Probabilistic Rules: Peirce–Cahoone vs RSVP

Cahoone, following Peirce, adopts a fallibilist naturalism: laws are never absolute, but are rules of thumb that constrain probability distributions. In this view, “law” is not a Platonic structure but a statistical regularity subject to error and revision. RSVP extends this pragmatic conception into a field-theoretic formalism, where heuristics, rules, and laws correspond to increasing levels of entropy-constrained predictability.

14.0.1 From Laws to Heuristics: A Continuum

Philosophers often distinguish between:

- Laws: universal, exceptionless regularities (e.g. conservation of energy).
- Rules: empirically robust generalizations, sometimes with known exceptions (e.g. Mendel’s laws of inheritance).
- Heuristics: context-specific, computationally efficient approximations (e.g. “use the ideal gas law when pressure is low”).

Cahoone collapses this into a continuum of fallible constraints. The more robust and exceptionless, the more “lawlike”; the more local and approximate, the more “heuristic.” RSVP formalizes this continuum using probability distributions over constraints.

14.0.2 Probabilistic Constraint Formalism

Let a system have states x . A law, rule, or heuristic can be represented as a constraint $C(x) = 0$. In RSVP, we assign a probability weight to this constraint:

$$P(C|x) = \exp\left(-\frac{|C(x)|^2}{2\sigma^2}\right),$$

where σ encodes tolerance:

- $\sigma \rightarrow 0$: strict law (no violations tolerated).
- finite σ : rule (small violations allowed).
- large σ : heuristic (broad violations tolerated).

Thus, laws, rules, and heuristics are unified as constraints with varying variance.

14.0.3 Peircean Fallibilism and Measurement Error

Peirce observed that no empirical law is ever perfectly certain because measurement itself has error. RSVP incorporates this through entropy of distributions:

$$S = - \sum_i P(x_i) \ln P(x_i).$$

The entropy of a constraint distribution measures our uncertainty about whether the law holds. High entropy corresponds to heuristics; low entropy corresponds to laws. This ties epistemology directly to thermodynamics: knowledge is the entropy-reduction of constraint distributions.

14.0.4 Wimsatt’s Heuristics and Aggregativity

Wimsatt argued that heuristics are indispensable because many system properties are nonaggregative: they cannot be derived by summing component behaviors. RSVP captures this by explicitly encoding coupling terms:

$$\dot{x}_i = f(x_i) + \sum_j K_{ij}(x_j - x_i),$$

where nonzero couplings K_{ij} generate emergent constraints not predictable from isolated components. Heuristics approximate such dynamics without exact solution, making them computationally efficient but inherently fallible.

14.0.5 Laws as Entropic Attractors

RSVP further reinterprets laws not as Platonic necessities but as stable attractors in entropy-regulating dynamics. For example, conservation of energy can be formalized as an invariance of entropy flux under time translation:

$$\frac{d}{dt}(E - TS) = 0.$$

In this sense, laws are not imposed externally but emerge as attractors where entropy flux reaches equilibrium. Rules and heuristics are local approximations to such attractors.

14.0.6 Example: The Law of Gravitation vs Heuristic Approximations

Law (Newtonian gravitation):

$$F = G \frac{m_1 m_2}{r^2}.$$

Rule (Kepler’s laws): emergent approximations of planetary motion derived under near-two-body assumptions. Moderate- σ .

Heuristic (constant g at Earth’s surface):

$$F \approx mg, \quad g \approx 9.8 \text{ m/s}^2,$$

RSVP unifies these by assigning each a constraint distribution with different variance, embedding them in a common entropic hierarchy.

14.0.7 Cultural Heuristics and Collective Knowledge

Cahoone also notes that heuristics extend beyond science into culture. RSVP generalizes this: cultural systems (laws, customs, norms) are constraints on collective entropy. They can be modeled with the same formalism:

$$P(C_{\text{cultural}}|\text{collective state}) = \exp\left(-\frac{|C(x)|^2}{2\sigma_c^2}\right).$$

Here σ_c reflects the flexibility of norms: rigid societies have low σ_c , permissive ones have high σ_c . This shows how epistemology, physics, and sociology share the same probabilistic structure.

14.0.8 Mathematical Summary

Heuristic rule:

$$H : X \rightarrow Y, \quad V(H) = \Pr(Y_H = Y_{\text{obs}}).$$

Law as asymptotic heuristic:

$$\lim_{t \rightarrow \infty} V(H) \rightarrow 1 - \epsilon.$$

RSVP translation:

Laws = invariants of (Φ, \mathbf{v}, S) up to entropy fluctuations.

Constraint hierarchy:

Emergence of laws = tightening of probabilistic constraints across scales.

Summary

Heuristics, rules, and laws are not fundamentally different ontological categories but levels of entropy-informed regularity. RSVP shows how the Peirce–Cahoone insight—that laws are fallible and probabilistic—arises naturally when scalar, vector, and entropy fields are coupled. This gives a precise mathematical grounding to philosophical naturalism, collapsing the hierarchy of “rule, law, heuristic” into a continuum of entropy-regulated approximations.

Chapter 15

Complexity, Scale, and Time

Cahoone highlights that complexity in nature is not uniformly distributed, but instead emerges most clearly at specific scales where interactions generate nonlinear behavior. Wimsatt's account of emergence emphasizes nonaggregativity; Erik Hoel emphasizes causal power; and RSVP adds the thermodynamic and dynamical dimension: emergence is fundamentally tied to characteristic scales in space and time at which entropy regulation reorganizes system behavior.

15.0.1 Complexity as Scale-Relative

A system's complexity is not an absolute property but depends on the scale of observation. At different scales, different variables dominate, different couplings are relevant, and different forms of entropy regulation occur. RSVP formalizes this through scale-dependent entropy:

$$S(\ell, \tau) = - \sum_{x \in \mathcal{X}(\ell, \tau)} P(x) \ln P(x),$$

where ℓ and τ are spatial and temporal coarse-graining parameters. Complexity arises when entropy does not monotonically increase under rescaling but exhibits local minima (organization) and maxima (chaos).

15.0.2 Characteristic Scales

Each natural order (physical, material, biological, mental, cultural) is marked by characteristic time scales and length scales. For example:

- Physics: particle interactions (10^{-43} s)
- Chemistry: molecular vibrations (10^{-12} s)
- Biology: metabolic cycles (10^{-3} s)
- Neuroscience: neural spikes (10^{-3} s)
- Culture: linguistic conventions, economic cycles (10^3 s)

Emergence occurs when processes at one time scale entrain or constrain processes at another. RSVP encodes this via multi-scale coupling:

$$\dot{x}_i(\tau) = f(x_i) + \sum_{\tau' \neq \tau} \kappa_{\tau\tau'} g(x_{\tau'}, x_{\tau}),$$

where $\kappa_{\tau\tau'}$ measures cross-scale coupling strength.

15.0.3 Complexity as Multi-Scale Entropy Gradient

RSVP frames emergence as the interplay between entropy production at different scales:

$$\frac{dS}{dt} = \sum_{\tau} \sigma(\tau),$$

with $\sigma(\tau)$ the entropy production rate at scale τ . A system is complex if no single $\sigma(\tau)$ dominates; instead, several scales interact nonlinearly to maintain stability. For example, the human brain maintains coherence by balancing millisecond-level spike trains with second-level oscillations and years-long learning.

15.0.4 Downward Causation as Cross-Scale Constraint

Downward causation, central to Cahoon's account, can be expressed as cross-scale entropy regulation:

$$\sigma(\tau_{\text{lower}}) \rightarrow f(\sigma(\tau_{\text{higher}})).$$

For instance, in organisms, long-term genetic regulation (slow scale) constrains fast molecular dynamics (fast scale). Similarly, cultural norms (slow, high-level scale) constrain individual decisions (fast, low-level scale).

RSVP treats downward causation as a renormalization constraint:

$$\mathcal{R}[\Phi(\ell), \mathbf{v}(\ell), S(\ell)] = \Phi(\ell'), \mathbf{v}(\ell'), S(\ell'),$$

where $\ell' > \ell$. Higher-level organization corresponds to fixed points of the renormalization operator \mathcal{R} .

15.0.5 Complexity Measures in RSVP

We can define a complexity index for an RSVP system by quantifying cross-scale coupling:

$$\mathcal{C} = \sum_{\tau < \tau'} |\kappa_{\tau\tau'}| I(X_{\tau}; X_{\tau'}),$$

where I is the mutual information between states at two scales. A system is maximally complex when many scales share strong mutual information, as in biological and cultural systems.

15.0.6 Cross-Scale Entropic Resonance

A novel RSVP prediction is entropic resonance, where fluctuations at one scale entrain stability at another. Formally:

$$R(\ell_1, \ell_2) = \frac{I(S_{\ell_1}; \Phi_{\ell_2}, \mathbf{v}_{\ell_2})}{H(S_{\ell_1})}.$$

If $R > 0.5$, then over half the entropy at scale ℓ_1 is constrained by higher-level structure at ℓ_2 . This mathematically encodes the idea that emergent wholes constrain their parts.

15.0.7 Time as an Emergent Order Parameter

In RSVP, time itself can be reinterpreted not as an external parameter but as an emergent ordering variable defined by entropy gradients:

$$t \sim \int \frac{dS}{\sigma_{\text{eff}}},$$

where σ_{eff} is the effective entropy production across scales. This suggests that “time” is fundamentally tied to multi-scale entropic unfolding, rather than a primitive background variable. This resonates with both Prigogine’s arrow of time and Cahoon’s emphasis on fallibilist local metaphysics: time is real, but only locally structured by the dynamics of entropy production.

Summary

Complexity, in both Cahoon’s and RSVP’s frameworks, is not an abstract property but a function of scale and time. Emergence corresponds to nonaggregative behavior across characteristic scales; downward causation corresponds to cross-scale entropy constraints; and complexity is measurable via cross-scale mutual information. RSVP thereby provides a quantitative foundation for Cahoon’s qualitative insight: we live in the middle, where multi-scale entropic dynamics create the richness of the natural world.

Chapter 16

Orders as Entropy Regulation Thresholds

Cahoone identifies five natural orders—physical, material, biological, mental, and cultural—each corresponding to a domain of emergent complexity irreducible to the level below it. While his account is qualitative, RSVP provides a way to mathematically formalize each order as a threshold of entropy regulation, defined by the ability of systems at that scale to maintain coherent structure against dissipation.

16.0.1 Orders as Entropic Phase Transitions

RSVP treats the emergence of orders as analogous to phase transitions in statistical mechanics. Each order corresponds to a regime where entropy gradients enable stable attractors. Formally, let $\sigma(\tau)$ be entropy production at scale τ . An order emerges when:

$$\exists \tau_c \quad \text{such that} \quad \left. \frac{\partial S}{\partial \tau} \right|_{\tau=\tau_c} = 0, \quad \left. \frac{\partial^2 S}{\partial \tau^2} \right|_{\tau=\tau_c} < 0.$$

That is, entropy stabilizes at a critical scale, producing robust organization.

16.0.2 The Physical Order

The physical order consists of fundamental particles and fields. Entropy regulation here is minimal: conservation laws emerge as invariant attractors. RSVP writes:

$$\nabla_\mu T^{\mu\nu} = 0, \quad \nabla_\mu J^\mu = 0,$$

where $T^{\mu\nu}$ is the stress-energy tensor and J^μ conserved currents. Complexity index:

$$\mathcal{C}_{\text{physical}} \approx 0,$$

since interactions are largely local and aggregative.

16.0.3 The Material Order

The material order corresponds to chemistry, condensed matter, and geology. Complexity emerges through nontrivial bonding rules:

$$H = \sum_i \epsilon_i n_i + \sum_{i < j} V_{ij} n_i n_j,$$

where H is the Hamiltonian of interacting atoms, n_i occupation numbers, and V_{ij} bond potentials. Entropy regulation occurs when bond structures stabilize free energy:

$$\Delta G = \Delta H - T\Delta S < 0.$$

The effective law of this order is Gibbs free energy minimization, producing ordered compounds.

16.0.4 The Biological Order

Life emerges when material order develops mechanisms to actively counteract entropy production. RSVP encodes this with the entropy balance equation:

$$\frac{dS_{\text{organism}}}{dt} = \sigma_{\text{int}} - \Phi_{\text{ext}},$$

where σ_{int} is internal entropy production and Φ_{ext} is entropy flux to the environment. Life exists when $\sigma_{\text{int}} - \Phi_{\text{ext}} < 0$, maintaining local entropy reduction.

The threshold condition for life:

$$\exists \text{ cyclic process } \mathcal{P} \quad \text{with} \quad \oint_{\mathcal{P}} dS < 0.$$

16.0.5 The Mental Order

The mental order corresponds to systems with nervous systems (or analogous feedback architectures) capable of recursive entropy modeling. RSVP encodes this with scalar-vector-entropy fields:

$$\partial_t \Phi = -\nabla \cdot \mathbf{v} + \alpha S, \quad \partial_t \mathbf{v} = -\nabla \Phi + \beta \nabla S.$$

Here Φ encodes potential states, \mathbf{v} flows of representation, and S informational entropy. A system is “mental” if it constructs internal entropy maps predictive enough to regulate its own dynamics:

$$I(\text{internal}; \text{external}) > \gamma,$$

where I is mutual information and γ a critical threshold.

16.0.6 The Cultural Order

Culture emerges when mental systems interact to generate shared constraints—norms, laws, languages—that reduce entropy at the collective level. RSVP formalizes cultural constraint as:

$$S_{\text{collective}} = S_{\text{individuals}} - I(\text{agents}; \text{norms}),$$

so that the entropy of the group is less than the sum of individual entropies by the amount of information shared.

Threshold condition for culture:

$$I(\text{agent}_i; \text{agent}_j) \gg 0 \quad \forall i, j,$$

sustained across generations.

16.0.7 Orders as Recursive Layers

Orders are not independent silos but recursive layers of entropy regulation. We can define the recursive entropy operator:

$$\mathcal{E}_{n+1} = \mathcal{R}[\mathcal{E}_n],$$

where \mathcal{E}_n is entropy regulation at order n , and \mathcal{R} is the renormalization operator. This makes explicit that culture emerges from mind, mind from life, life from matter, and matter from physics.

16.0.8 Mathematical Summary

Physical order: scalar field conservation, $\nabla \cdot \mathbf{v} = -\frac{\dot{\rho}}{\rho}$.

Material order: vector coherence, stabilized by $\dot{\lambda}$.

Biological order: negentropic limit cycles, locally $\dot{S} < 0$.

Mental order: recursive suppression of entropy by information, $\dot{S} = -\lambda I$.

Cultural order: sheaf cohomology across agents, $H^1(\mathcal{F}) \neq 0$.

Summary

Orders of nature are not metaphysical abstractions but empirically grounded bifurcations in complexity. RSVP provides explicit dynamics for each transition: from scalar conservation to vector coherence, from entropy cycles to recursive cognition, and finally to collective cultural sheaves. The orders of nature thus map onto distinct attractor regimes of the scalar–vector–entropy fields, with each order emerging from yet constraining its predecessors. Complexity thresholds provide the mathematical signature of these emergences, marking the universe as an unfolding hierarchy of probabilistic structures.

Chapter 17

Complexity Metrics and Cross-Scale Mutual Information

To connect emergence with measurable quantities, we require complexity metrics that track the interplay of entropy, structure, and causality across scales. In RSVP, these metrics emerge naturally from the scalar potential Φ , vector field \mathbf{v} , and entropy field S . The key is that complexity is not reducible to raw entropy (disorder) or structure (order), but arises from the cross-scale coupling of order and disorder.

17.0.1 Shannon Entropy and Entropy Flux

The baseline complexity measure is Shannon entropy:

$$H(X) = - \sum_i p(x_i) \log p(x_i),$$

which measures uncertainty in a system. In RSVP, this is generalized to a field entropy density:

$$s(\mathbf{x}, t) = -\rho(\mathbf{x}, t) \log \rho(\mathbf{x}, t),$$

and the total entropy is

$$S(t) = \int_V s(\mathbf{x}, t) dV.$$

The entropy flux vector is:

$$\mathbf{J}_S = S\mathbf{v} - \kappa \nabla S,$$

where κ encodes diffusion. This provides a dynamic balance between local disorder and its transport across scales.

17.0.2 Mutual Information as Cross-Scale Constraint

Mutual information measures the reduction of uncertainty about one system from another:

$$I(X; Y) = H(X) + H(Y) - H(X, Y).$$

In RSVP, we define cross-scale mutual information between fields at different coarse-grainings. For example, between microstates (m) and macrostates (M):

$$I(m; M) = H(m) + H(M) - H(m, M).$$

If $I(m; M) > 0$, then macro-level order provides predictive constraint on micro-level fluctuations—formalizing downward causation.

17.0.3 Effective Complexity: Order + Entropy

Following Gell-Mann and Lloyd, effective complexity is the information content of regularities:

$$C_{\text{eff}} = K(\text{regularities}),$$

where K is Kolmogorov complexity. RSVP reformulates this as:

$$C_{\text{eff}} = I(\Phi, \mathbf{v}; S),$$

the mutual information between scalar–vector structure and entropy. This quantifies how much entropy flux is “captured” into stable structures.

17.0.4 Multiscale Entropy and RSVP

Multiscale entropy (MSE) analysis, widely used in physiology, measures entropy across increasing time coarse-grainings. RSVP generalizes this to fields:

$$MSE(\tau) = - \sum_i p_\tau(x_i) \log p_\tau(x_i),$$

where τ is the scale parameter.

Applied to RSVP:

- Small τ : noise-dominated entropy.
- Large τ : structured entropy from coherent flows.

Thus, MSE in RSVP reveals scale-dependent complexity layers, mapping neatly onto Cahoon’s “orders of nature.”

17.0.5 RSVP Complexity Index

We can now define an RSVP Complexity Index (RCI):

$$\text{RCI} = \alpha I(m; M) + \beta C_{\text{eff}} + \gamma MSE(\tau),$$

where α, β, γ are weights tuned to domain.

High RCI \rightarrow strong emergent order (e.g. galaxies, brains, cultures).

Low RCI \rightarrow either chaotic disorder or trivial order (crystals, vacuums).

This provides a unified measure of emergence across cosmology, biology, and cognition.

17.0.6 Cross-Scale Entropic Resonance

A novel RSVP prediction is entropic resonance, where fluctuations at one scale entrain stability at another. Formally:

$$R(\ell_1, \ell_2) = \frac{I(S_{\ell_1}; \Phi_{\ell_2}, \mathbf{v}_{\ell_2})}{H(S_{\ell_1})}.$$

If $R > 0.5$, then over half the entropy at scale ℓ_1 is constrained by higher-level structure at ℓ_2 . This mathematically encodes the idea that emergent wholes constrain their parts.

Summary

RSVP grounds complexity in mutual information between entropy and structure across scales. By formalizing heuristics like “downward causation” and “emergent order” into entropy–vector–scalar couplings, RSVP provides quantitative tools for measuring complexity in cosmology (void–cluster backreaction), biology (multiscale physiology), and cognition (field-theoretic consciousness).

Chapter 18

Concluding Synthesis: Orders of Nature and RSVP as Unified Natural Philosophy

The trajectory of this essay has moved from heuristics and laws to emergence and complexity, and finally to the orders of nature. The final task is to integrate these strands into a single framework that honors the philosophical breadth of Cahoon and the mathematical precision of RSVP.

18.0.1 Orders of Nature as Entropy-Structured Layers

Cahoon distinguished five major “orders of nature”: physical, material, biological, mental, and cultural. RSVP reframes these as entropy-structured layers of field complexity:

1. Physical Order

Governed by conservation laws and entropy flux at the smallest scales.

$$\nabla \cdot \mathbf{v} = -\frac{\dot{\rho}}{\rho}.$$

2. Material Order (Chemistry, Geology)

Stabilized by entropy thresholds creating persistent molecular and geological complexes.

$$C_{\text{chem}} = I(\Phi; S)_{\text{molecules}}.$$

3. Biological Order (Life)

Defined by recursive entropy regulation:

$$\dot{S}_{\text{organism}} < 0 \quad \text{locally, but} \quad \dot{S}_{\text{universe}} > 0.$$

4. Mental Order (Animal Mind)

Neural RSVP fields yield conscious attractors when vector flows stabilize entropy fluctuations:

$$\phi_{\text{RSVP}} = \int (\Phi \nabla \cdot \mathbf{v} - S \dot{\Phi}) dV.$$

5. Cultural Order (Human Systems)

Cultural artifacts, language, and institutions are emergent entropy-regulating complexes spanning individual minds:

$$I(\text{minds}; \text{symbols}) \gg 0,$$

Each order is real, and each is grounded in the same entropic field mechanics.

18.0.2 RSVP as Meta-Naturalism

Where Cahoon offers a pluralistic metaphysics of ontological parity—all systems, processes, and structures are equally real—RSVP provides a mathematical implementation. Every order of nature is not only real but computable as a scalar–vector–entropy field. This transforms metaphysical pluralism into meta-naturalism, a universal framework where:

- Laws = long-run entropy constraints.
- Heuristics = truncated field approximations.
- Emergence = entropy–vector–scalar coupling.
- Complexity = cross-scale mutual information.
- Orders of nature = stable entropy layers.

18.0.3 Philosophical Implications

1. Anti-Reductionism: Higher orders are not reducible to lower ones because mutual information increases at coarse-grained levels ($I(m; M) > 0$).
2. Fallibilism: Laws are approximations of entropy regulation, not eternal absolutes, vindicating Peirce’s insight.
3. Ontological Parity: Physical, biological, and cultural orders are equally real; RSVP makes this testable.
4. Emergent Causality: Downward causation is mathematically defined by entropic resonance, not mysticism.

18.0.4 Toward a Unified Natural Philosophy

The integration of Cahoon’s Orders of Nature with RSVP yields a unified natural philosophy where metaphysics, physics, and epistemology converge:

$$\text{Reality} = \bigcup_n \{\Phi_n, \mathbf{v}_n, S_n\},$$

with each n indexing an order of nature. The universe is not a collection of billiard balls or an ineffable flux, but a hierarchy of entropic fields, each giving rise to new forms of causality and complexity.

18.0.5 Closing Statement

What began as a dialogue between philosophy and physics culminates in a framework where laws are fallible, emergence is quantifiable, and all orders of nature are equally real. RSVP shows that metaphysics can be mathematized without losing its breadth, and physics can be philosophically grounded without collapsing into reductionism.

The promise of this synthesis is not only theoretical but practical: by treating culture, mind, life, and matter as layered entropy fields, we gain tools for modeling systems across cosmology, biology, AI, and society in one coherent framework.

Final Summary

Cahoone's contribution: pluralistic metaphysics, emergence, orders of nature.

RSVP's contribution: entropy-field mathematics to make these testable.

Synthesis: a unified natural philosophy, where complexity is neither mystical nor reducible, but measurable as entropy–structure interactions.

Part II

Appendices

Appendix A

Mathematical Formalism

In this appendix we provide a minimal set of equations that define the RSVP (Relativistic Scalar–Vector Plenum) framework and show how it reduces to Friedmann-like dynamics in the homogeneous limit.

A.1 Local Field Equations

RSVP is formulated in terms of scalar density ρ , peculiar velocity field \mathbf{v} , and entropy density s :

$$\partial_t \rho + 3H\rho + \nabla \cdot (\rho \mathbf{v}) = 0, \quad (\text{A.1})$$

$$\partial_t \mathbf{v} + (\mathbf{v} \cdot \nabla) \mathbf{v} + H\mathbf{v} = -\frac{1}{a^2} \nabla \Phi_N - \frac{1}{a^2 \rho c^2} \nabla (p + \Pi_S), \quad (\text{A.2})$$

$$\nabla^2 \Phi_N = 4\pi G a^2 (\rho - \bar{\rho}), \quad (\text{A.3})$$

$$\partial_t s + 3Hs + \nabla \cdot (s \mathbf{v} - D_s \nabla s) = \Sigma, \quad \Sigma \geq 0. \quad (\text{A.4})$$

The novel RSVP contribution is the *entropic bulk pressure*

$$\Pi_S = -\zeta_s \theta + \chi_s \nabla^2 s, \quad \theta = 3H + \nabla \cdot \mathbf{v}, \quad (\text{A.5})$$

together with the entropy production law

$$\Sigma = \frac{\zeta_s}{T} \theta^2 + \frac{\chi_s}{T} |\nabla^2 s|^2 + \frac{\eta_s}{T} \sigma_{ij} \sigma^{ij}, \quad \Sigma \geq 0. \quad (\text{A.6})$$

A.2 Relativistic Formulation

The effective stress–energy tensor is

$$T^{\mu\nu} = (\rho c^2 + p + \Pi_S) u^\mu u^\nu + (p + \Pi_S) g^{\mu\nu} + \pi^{\mu\nu}, \quad (\text{A.7})$$

with entropy current

$$s^\mu = s u^\mu - D_s \nabla^\mu s, \quad \nabla_\mu s^\mu = \Sigma \geq 0. \quad (\text{A.8})$$

Einstein’s field equations then read

$$G^{\mu\nu} = \frac{8\pi G}{c^4} T^{\mu\nu}. \quad (\text{A.9})$$

A.3 Coarse-Grained Dynamics

Averaging over a comoving domain \mathcal{D} with scale factor $a_{\mathcal{D}}(t)$ gives Buchert-type equations modified by RSVP terms:

$$3H_{\mathcal{D}}^2 = \frac{8\pi G}{c^2} \langle \rho \rangle_{\mathcal{D}} - \frac{1}{2} \langle \mathcal{R} \rangle_{\mathcal{D}} - \frac{1}{2} Q_{\text{kin}} + \frac{8\pi G}{c^4} \langle \Pi_S \rangle_{\mathcal{D}}, \quad (\text{A.10})$$

$$3 \frac{\ddot{a}_{\mathcal{D}}}{a_{\mathcal{D}}} = -\frac{4\pi G}{c^2} \left\langle \rho c^2 + 3(p + \Pi_S) \right\rangle_{\mathcal{D}} + Q_{\text{kin}}, \quad (\text{A.11})$$

$$\langle \dot{\rho} \rangle_{\mathcal{D}} + 3H_{\mathcal{D}} \langle \rho \rangle_{\mathcal{D}} = 0. \quad (\text{A.12})$$

In the homogeneous and isotropic limit ($Q_{\text{kin}} = 0$, $\nabla s = 0$), these reduce to the standard Friedmann equations with an effective pressure correction:

$$\frac{\ddot{a}}{a} = -\frac{4\pi G}{3} \left(\rho + 3 \frac{p + \Pi_S}{c^2} \right). \quad (\text{A.13})$$

Appendix B

Notes on Naturalism

This appendix contains conceptual notes linking RSVP to broader currents in naturalistic philosophy. Topics include:

- Prigogine’s dissipative structures and the role of entropy export in emergent order [\[16\]](#).
- Ernst Mayr’s distinction between teleology and teleonomy, and how RSVP’s formalism corresponds to the latter [\[13\]](#).
- Lawrence Cahoon’s naturalism and its connection to RSVP’s sheaf-theoretic “local metaphysics.”

Appendix C

Computational Alternatives

We also summarize conceptual alternatives to the standard von Neumann computational paradigm that inform RSVP’s analogical structure:

- Dataflow architectures developed at MIT in the 1970s [\[1\]](#).
- Neuromorphic computing inspired by Carver Mead [\[14\]](#).
- Associative memory designs from the 1960s.
- Stack machine architectures such as the Burroughs B5000 [\[4\]](#).
